Abstraction /

"Models are approximations to reality / absolute truth / system / phenomenon."

- model airplane → airplane → allows engineers to evaluate the real product
- map → locations of streets in a city → allows you to find your way
- wind tunnel → fast moving air → allows for testing vehicles traveling at high speeds
- early school, early to rise, make a man healthy, wealthy & wise → success of human beings → allows for testing vehicle

George Box "All models are wrong but some are useful"

Models are useful for two grand goals:

- 1 Prediction → what will happen in the real world under set of conditions
- 2 Exploration → when makes this model tick?

become dog's
not reality

they serve some
useful function
Even though dog's
not reality

"Data" is the ^{hasml} result of system or phenomenon which is "measured".

"Validation" is the comparison of the "data" to the "prediction" from the model. If data and predictions are "close", the model is "good". If not, we can rebuild/improve the model. The process is usually iterative.

Early to bed, early to rise makes a man healthy really & wise."

Who is this saying?

a means of combining the inputs to produce the outputs, i.e. a functional relationship

What goes on inside of me?

well, the content of bedtime \Rightarrow

all 3 outputs increase, the content of wake time \Rightarrow all 3 outputs increase

This aphorism is extremely incoherent / ambiguous!

Why?

- bedtime ill-defined
- wake time "
- healthy "
- wisdom "
- f "

Why function? It should make sense to get two different versions of health, or wake up? (will see soon enough)

How to make this exact?

How to measure?

- define bedtime as 24 hr time (avg?) (b)
 - " " " " (avg?) (w)
 - define health as longevity (L)
 - define wisdom as ~~test~~ worth at age 60 (L)
 - define wisdom as... good luck! Create a test and measure a score! (S)
- provide functional form of m

\Rightarrow Mathematical model \subset models

Where inputs & outputs are numerical quantities related by an explicit sign

models

mathematical models

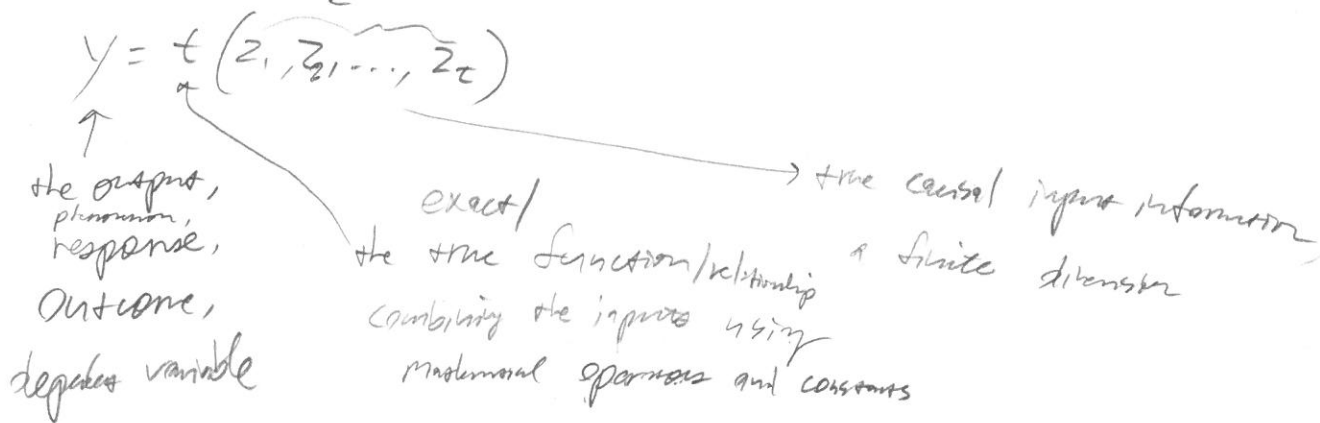

Mathematical models are ideas, not concrete such as the model airplane.
 We've been building mathematical models since ≈ 2000 BC. We're pretty good at them:

$$\begin{array}{cccc} F = ma, & E = mc^2 \\ \uparrow & \uparrow\uparrow & \uparrow & \uparrow\uparrow \\ \text{input inputs} & & & \end{array}$$

Physics, Chemistry, Economics, ... all disciplines use them.

This rests on an assumption: that the world is explicable mathematically.
 We will agree for the purposes of this course to believe this.

In which case, all phenomena can be described via:

For the purposes of this class we will assume this is one-dimensional

Note that we assume y exactly equals $f(\vec{z})$ which means the phenomenon is perfectly explicable

There are those who debate determinism, but it's beside the point for the purposes of this class

e.g. the canonical example is a model which explains "creditworthiness" for a credit application for Bob here

$$y \in \{ \text{creditworthy}, \text{uncreditworthy} \}$$

If we build a mathematical model, y must be a #.

7

$$\Rightarrow y \in \{0, 1\} = \text{Categorical (pay back loan)} = y \text{ (the output space)}$$

The inputs, z_1, z_2, \dots, z_t are characteristics about a person.

What are the characteristics that are causal? I don't know, but e.g.

z_1 : ^{bb} has sufficient funds to pay back loan at ^{the} time it is due $\in \{0, 1\}$

z_2 : ^{bb} has ~~any~~ emergency, occur during this time $\in \{0, 1\}$

z_3 : ^{bb} has criminal intentions $\in \{0, 1\}$

$$y = t(z_1, z_2, z_3) = z_1(1 - z_2)(1 - z_3)$$

If you had z_1, z_2, z_3 then t you can explain y exactly? YES.

Do you have z_1, z_2, z_3 ? No... they are inputs assessed in the future and the future hasn't happened yet or they are impossible to assess.

Criminal intention? How do you measure that??

Further, in general, we don't know t either. In the mock situation here, we do. (Secondary problem)

Primary problem is you can't observe the truly causal input information.

What's the next best thing? Get information inputs that best approximate the z 's.

X_1 : Salary. How to measure: historical avg. salary?

X_2 : previous loan repayments. How to measure: did they ever miss a payment?

X_3 : historical criminal record. How to measure: previous crime type?
